

Asset Management and Risk Classification

1. Project description

In this project, I created an inventory of devices connected to a home office network and classified them based on their sensitivity and business impact. The goal was to identify assets that require additional protection and apply appropriate classifications to support risk management and security planning.

2. Asset Identified

A) Network Router

- network access : continuous
- Owner : Internet Service Provider
- Location : on-premises
- Classification : Confidential

Reason: The router provides connectivity for all devices on the network and represents a critical infrastructure component.

B) Desktop Computer

- network access : occasional
- Owner : Homeowner
- Location : on-premises
- Classification : Restricted

Reason: Contains personal information, files, and sensitive data requiring the highest level of protection.

C) Guest Smartphone

- network access : occasional
- Owner : guest
- Location : on-premises and off-premises
- Classification : Internal only

Reason: Connects to the home network but doesn't store sensitive organizational information.

D) External Hard Drive

- network access : occasional
- Owner : Homeowner
- Location : on-premises
- Classification : Confidential

Reason: Stores media files and potentially valuable personal content.

E) Streaming media device

- network access : continuous
- Owner : Homeowner
- Location : on-premises
- Classification : internal only

Reason: Contains account information and access to subscription services.

F) Portable Game Console

- network access : occasional
- Owner : Guest
- Location : on-premises and off-premises
- Classification : Internal only

Reason: Includes camera and microphone capabilities and connects to the local network.

3. Security Classifications used

Restricted - need-to-know basis

Confidential - Limited to specific authorized users

Internal - only Internal users only

Public - available to anyone

4. Skills demonstrated

- asset inventory management,
- Asset classification,
- Risk assessment,
- Data classification,
- Security governance,
- Asset identification,
- Security documentation,
- Information security fundamentals.

5. Summary

This process focused on identifying, documenting, and classifying assets connected to a home office network. I evaluated each asset based on ownership, location, network access, and sensitivity level. The exercise demonstrated how asset management supports risk reduction by helping organizations understand which assets require stronger security controls and protection measures.
